

HYBRIDIZATION ASSAY USING  
SELF-QUENCHING FLUORESCENCE PROBE

ABSTRACT

10 A hybridization assay is provided which uses an oligonucleotide probe  
which includes a fluorescent reporter molecule and a quencher molecule  
capable of quenching the fluorescence of the reporter molecule. The  
oligonucleotide probe is constructed such that the probe exists in at least one  
single-stranded conformation when unhybridized where the quencher molecule  
15 is near enough to the reporter molecule to quench the fluorescence of the  
reporter molecule. The oligonucleotide probe also exists in at least one  
conformation when hybridized to a target polynucleotide where the quencher  
molecule is not positioned close enough to the reporter molecule to quench the  
fluorescence of the reporter molecule. By adopting these hybridized and  
20 unhybridized conformations, the reporter molecule and quencher molecule on  
the probe exhibits different fluorescence signal intensities when the probe is  
hybridized and unhybridized. As a result, it is possible to determine whether the  
probe is hybridized or unhybridized based on a change in the fluorescence  
intensity of the reporter molecule, the quencher molecule, or a combination  
25 thereof. In addition, because the probe can be designed such that the quencher  
molecule quenches the reporter molecule when the probe is not hybridized, the  
probe can be designed such that the reporter molecule exhibits limited  
fluorescence until the probe is either hybridized or digested.
